## Layers.py

This file contains all of the code contained in the layers.py file.

## Code

```
import numpy as np
def affine_forward(x, w, b):
 Computes the forward pass for an affine (fully-connected) layer.
 The input x has shape (N, d_1, \ldots, d_k) and contains a minibatch of N
 examples, where each example x[i] has shape (d_1, \ldots, d_k). We will
 reshape each input into a vector of dimension D = d_1 * ... * d_k, and
 then transform it to an output vector of dimension M.
 Inputs:
 -x: A numpy array containing input data, of shape (N, d_1, \ldots, d_k)
 - w: A numpy array of weights, of shape (D, M)
 - b: A numpy array of biases, of shape (M,)
 Returns a tuple of:
 - out: output, of shape (N, M)
 - cache: (x, w, b)
 # ----- #
 # YOUR CODE HERE:
   Calculate the output of the forward pass. Notice the dimensions
 # of w are D \times M, which is the transpose of what we did in earlier
    assignments.
 x_shapes = x.shape
 D = np.prod(x_shapes[1:])
 N = x_shapes[0]
 X = x.reshape(N,D)
 out = X@w+b
 # ------ #
 # END YOUR CODE HERE
 cache = (x, w, b)
```

## return out, cache

```
def affine_backward(dout, cache):
 Computes the backward pass for an affine layer.
 Inputs:
 - dout: Upstream derivative, of shape (N, M)
 - cache: Tuple of:
   - x: A number array containing input data, of shape (N, d_1, \ldots, d_k)
   - w: A numpy array of weights, of shape (D, M)
   - b: A numpy array of biases, of shape (M,)
 Returns a tuple of:
 - dx: Gradient with respect to x, of shape (N, d1, ..., d_k)
 - dw: Gradient with respect to w, of shape (D, M)
 - db: Gradient with respect to b, of shape (M,)
 x, w, b = cache
 dx, dw, db = None, None, None
 # YOUR CODE HERE:
 # Calculate the gradients for the backward pass.
 # Notice:
 # dout is N x M
    dx should be N x d1 x ... x dk; it relates to dout through multiplication with w, whi
 # dw should be D x M; it relates to dout through multiplication with x, which is N x D d
    db should be M; it is just the sum over dout examples
 # ------ #
 x_shapes = x.shape
 D = np.prod(x shapes[1:])
 N = x_shapes[0]
 x_reshape = x.reshape(N,D)
 dx = (dout@w.T).reshape(x_shapes)
 dw = x_reshape.T@dout
 db = dout.T@np.ones((N,))
 # ----- #
 # END YOUR CODE HERE
 return dx, dw, db
def relu_forward(x):
```

```
Computes the forward pass for a layer of rectified linear units (ReLUs).
 Input:
 - x: Inputs, of any shape
 Returns a tuple of:
 - out: Output, of the same shape as x
 - cache: x
 # ------ #
 # YOUR CODE HERE:
  Implement the ReLU forward pass.
 out = (x>0)*x
 # ============ #
 # END YOUR CODE HERE
 # ----- #
 cache = x
 return out, cache
def relu_backward(dout, cache):
 Computes the backward pass for a layer of rectified linear units (ReLUs).
 Input:
 - dout: Upstream derivatives, of any shape
 - cache: Input x, of same shape as dout
 Returns:
 - dx: Gradient with respect to x
 x = cache
 # YOUR CODE HERE:
 # Implement the ReLU backward pass
 # ----- #
 dx = dout*(x>0)
 # END YOUR CODE HERE
 # ----- #
```

return dx

```
def batchnorm_forward(x, gamma, beta, bn_param):
```

Forward pass for batch normalization.

During training the sample mean and (uncorrected) sample variance are computed from minibatch statistics and used to normalize the incoming data. During training we also keep an exponentially decaying running mean of the mean and variance of each feature, and these averages are used to normalize data at test-time.

At each timestep we update the running averages for mean and variance using an exponential decay based on the momentum parameter:

```
running_mean = momentum * running_mean + (1 - momentum) * sample_mean
running_var = momentum * running_var + (1 - momentum) * sample_var
```

Note that the batch normalization paper suggests a different test-time behavior: they compute sample mean and variance for each feature using a large number of training images rather than using a running average. For this implementation we have chosen to use running averages instead since they do not require an additional estimation step; the torch7 implementation of batch normalization also uses running averages.

```
Input:
```

```
- x: Data of shape (N, D)
- gamma: Scale parameter of shape (D,)
- beta: Shift paremeter of shape (D,)
- bn_param: Dictionary with the following keys:
  - mode: 'train' or 'test'; required
  - eps: Constant for numeric stability
  - momentum: Constant for running mean / variance.
  - running_mean: Array of shape (D,) giving running mean of features
  - running var Array of shape (D,) giving running variance of features
Returns a tuple of:
- out: of shape (N, D)
- cache: A tuple of values needed in the backward pass
mode = bn_param['mode']
eps = bn_param.get('eps', 1e-5)
momentum = bn_param.get('momentum', 0.9)

 return out, cache
def batchnorm_backward(dout, cache):
 Backward pass for batch normalization.
 For this implementation, you should write out a computation graph for
 batch normalization on paper and propagate gradients backward through
 intermediate nodes.
 Inputs:
 - dout: Upstream derivatives, of shape (N, D)
 - cache: Variable of intermediates from batchnorm_forward.
 Returns a tuple of:
 - dx: Gradient with respect to inputs x, of shape (N, D)
 - dgamma: Gradient with respect to scale parameter gamma, of shape (D,)
 - dbeta: Gradient with respect to shift parameter beta, of shape (D,)
 dx, dgamma, dbeta = None, None, None
 # ======= #
 # YOUR CODE HERE:
   Implement the batchnorm backward pass, calculating dx, dgamma, and dbeta.
 # ----- #
 N,D = dout.shape
 dbeta = np.ones(N,)@dout
 dgamma = np.ones(N,)@(dout*cache['xhat'])
```

```

   return dx, dgamma, dbeta
def dropout_forward(x, dropout_param):
   Performs the forward pass for (inverted) dropout.
    Inputs:
    - x: Input data, of any shape
    - dropout_param: A dictionary with the following keys:
        - p: Dropout parameter. We drop each neuron output with probability p.
        - mode: 'test' or 'train'. If the mode is train, then perform dropout;
            if the mode is test, then just return the input.
        - seed: Seed for the random number generator. Passing seed makes this
            function deterministic, which is needed for gradient checking but not in
           real networks.
    Outputs:
    - out: Array of the same shape as x.
    - cache: A tuple (dropout_param, mask). In training mode, mask is the dropout
       mask that was used to multiply the input; in test mode, mask is None.
   p, mode = dropout_param['p'], dropout_param['mode']
   if 'seed' in dropout param:
